But it's not really something we should fear either. It's nature. Temperature increases and decreases have been on this planet since over 9000 years.

bang your head against a wall. right now.

<http://www.skepticalscience.com/Empirical-evidence-that-humans-are-causing-global-warming.html>

I'm not about to read the whole thing, but at first sight it seems to be about changing temp. in like the last few centuries. Remember, the earth is 4.5 billion years old.

We can only go by what has been recorded. To move forward under the assumption that this is just a natural process that the earth is undergoing, AND that this natural process will not be harmful to us, is incredibly foolish. The other extreme is equally as foolish. The logical option is to proceed with caution until we know exactly what is causing these changes, and where these changes will lead us. Experimentation on a global scale based on the equation 'pollution = bad' seems like a good way to gather information imo.

Agreed. I'm just saying, the fact that the temp. is rising is only for a really small part caused by human pollution. The temperature has been changing way before there ever was such a thing as human pollution. Anyone remember the ice ages? Was that caused by human pollution? No. Therefore people should stop being so overdramatic about this whole thing. Didn't I tell you to bang your head against a wall? Why aren't you doing that yet!
